

General Description

The MAX6340/MAX6421-MAX6426 low-power microprocessor supervisor circuits monitor system voltages from 1.6V to 5V. These devices perform a single function: they assert a reset signal whenever the VCC supply voltage falls below its reset threshold. The reset output remains asserted for the reset timeout period after VCC rises above the reset threshold. The reset timeout is externally set by a capacitor to provide more flexibility.

The MAX6421/MAX6424 have an active-low, pushpull reset output. The MAX6422 has an active-high, push-pull reset output and the MAX6340/MAX6423/ MAX6425/MAX6426 have an active-low, open-drain reset output. The MAX6421/MAX6422/MAX6423 are offered in 4-pin SC70 or SOT143 packages. The MAX6340/MAX6424/MAX6425/MAX6426 are available in 5-pin SOT23-5 packages.

Features

- ♦ Monitor System Voltages from 1.6V to 5V
- ♦ Capacitor-Adjustable Reset Timeout Period
- ♦ Low Quiescent Current (1.6µA typ)
- **♦ Three RESET Output Options** Push-Pull RESET **Push-Pull RESET Open-Drain RESET**
- ♦ Guaranteed Reset Valid to V_{CC} = 1V
- ♦ Immune to Short V_{CC} Transients
- ♦ Small 4-Pin SC70, 4-Pin SOT143, and 5-Pin SOT23 **Packages**
- ♦ MAX6340 Pin Compatible with LP3470
- ♦ MAX6424/MAX6425 Pin Compatible with NCP300-NCP303, MC33464/MC33465, S807/S808/S809, and RN5VD
- **♦ MAX6426 Pin Compatible with PST92XX**

Ordering Information

PART	TEMP RANGE	PIN-PACKAGE

MAX6426UKT	-40°C to +125°C	5 SOT23-5

Note: The MAX6340/MAX6421-MAX6426 are available with factory-trimmed reset thresholds from 1.575V to 5.0V in approximately 0.1V increments. Insert the desired nominal reset threshold suffix (from Table 1) into the blanks. There are 50 standard versions with a required order increment of 2500 pieces. Sample stock is generally held on standard versions only (see Standard Versions Table). Required order increment is 10,000 pieces for nonstandard versions. Contact factory for availability. All devices are available in tape-and-reel only.

Typical Operating Circuit appears at end of data sheet.

Selector Guide appears at end of data sheet.

Detailed Description

Reset Output

The reset output is typically connected to the reset input of a $\mu P.$ A $\mu P's$ reset input starts or restarts the μP in a known state. The MAX6340/MAX6421–MAX6426 μP supervisory circuits provide the reset logic to prevent code-execution errors during power-up, power-down, and brownout conditions (see *Typical Operating Characteristics*).

RESET changes from high to low whenever V_{CC} drops below the threshold voltage. Once V_{CC} exceeds the threshold voltage, RESET remains low for the capacitor-adjustable reset timeout period.

The MAX6422 active-high RESET output is the inverse logic of the active-low $\overline{\text{RESET}}$ output. All device outputs are guaranteed valid for $V_{CC} > 1V$.

The MAX6340/MAX6423/MAX6425/MAX6426 are opendrain RESET outputs. Connect an external pullup resistor to any supply from 0 to 5.5V. Select a resistor value large enough to register a logic low when RESET is asserted and small enough to register a logic high while supplying all input current and leakage paths connected to the RESET line. A $10k\Omega$ to $100k\Omega$ pullup is sufficient in most applications.

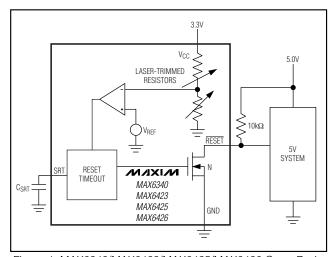

Figure 1. MAX6340/MAX6423/MAX6425/MAX6426 Open-Drain RESET Output Allows Use with Multiple Supplies

Selecting a Reset Capacitor

The reset timeout period is adjustable to accommodate a variety of μP applications. Adjust the reset timeout period (the property) by connecting a capacitor (CSRT) between SRT and ground. Calculate the reset timeout capacitor as follows:

 $C_{SRT} = (t_{RP} - 275\mu s) / (2.73 \times 10^6)$

where the is in seconds and CSRT is in farads.

The reset delay time is set by a current/capacitor-controlled ramp compared to an internal 0.65V reference. An internal 240nA ramp current source charges the external capacitor. The charge to the capacitor is cleared when a reset condition is detected. Once the reset condition is removed, the voltage on the capacitor ramps according to the formula: dV/dt = I/C. The CSRT capacitor must ramp to 0.65V to deassert the reset. CSRT must be a low-leakage (<10nA) type capacitor; ceramic is recommended.

Operating as a Voltage Detector

The MAX6340/MAX6421–MAX6426 can be operated in a voltage detector mode by floating the SRT pin. The reset delay times for VCC rising above or falling below the threshold are not significantly different. The reset output is deasserted smoothly without false pulses.

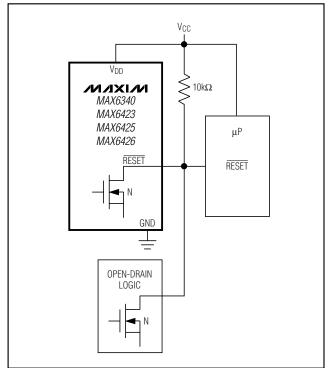

Figure 2. Wired-OR Reset Circuit

Applications Information

Interfacing to Other Voltages for Logic Compatibility

The open-drain outputs of the MAX6340/MAX6423/MAX6425/MAX6426 can be used to interface to μ Ps with other logic levels. As shown in Figure 1, the open-drain output can be connected to voltages from 0 to 5.5V. This allows for easy logic compatibility to various μ Ps.

Wired-OR Reset

To allow auxiliary circuitry to hold the system in reset, an external open-drain logic signal can be connected to the open-drain \overline{RESET} of the MAX6340/MAX6423/MAX6425/MAX6426, as shown in Figure 2. This configuration can reset the μP , but does not provide the reset timeout when the external logic signal is released.

Negative-Going Vcc Transients

In addition to issuing a reset to the μP during power-up, power-down, and brownout conditions, these supervisors are relatively immune to short-duration negative-going transients (glitches). The graph Maximum Transient Duration vs. Reset Threshold Overdrive in the *Typical Operating Characteristics* shows this relationship.

The area below the curve of the graph is the region in which these devices typically do not generate a reset pulse. This graph was generated using a negative-going pulse applied to V_{CC}, starting above the actual reset threshold (V_{TH}) and ending below it by the magnitude indicated (reset-threshold overdrive). As the magnitude of the transient decreases (farther below the reset threshold), the maximum allowable pulse width decreases. Typically, a V_{CC} transient that goes 100mV below the reset threshold and lasts 50µs or less does not cause a reset pulse to be issued.

Ensuring a Valid RESET or RESET Down to VCC = 0

When V_{CC} falls below 1V, RESET/RESET current-sinking (sourcing) capabilities decline drastically. In the case of the MAX6421/MAX6424, high-impedance CMOS-logic inputs connected to RESET can drift to undetermined voltages. This presents no problems in most applications, since most μ Ps and other circuitry do not operate with V_{CC} below 1V.

In those applications where $\overline{\text{RESET}}$ must be valid down to zero, adding a pulldown resistor between $\overline{\text{RESET}}$ and ground sinks any stray leakage currents, holding $\overline{\text{RESET}}$ low (Figure 3). The value of the pulldown resistor is not critical; $100\text{k}\Omega$ is large enough not to load $\overline{\text{RESET}}$ and small enough to pull $\overline{\text{RESET}}$ to ground. For applications using the MAX6422, a $100\text{k}\Omega$ pullup resistor

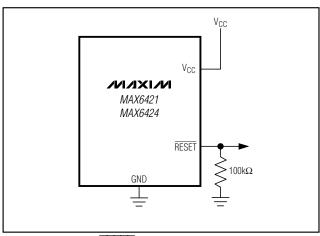

Figure 3. Ensuring \overline{RESET} Valid to $V_{CC} = 0$

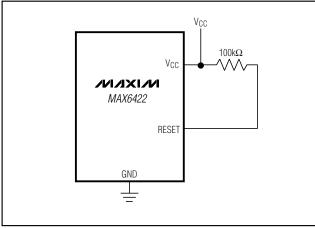

Figure 4. Ensuring RESET Valid to $V_{CC} = 0$

tor between RESET and V_{CC} holds RESET <u>high</u> when V_{CC} falls below 1V (Figure 4). Open-drain RESET versions are not recommended for applications requiring valid logic for V_{CC} down to zero.

Layout Consideration

SRT is a precise current source. When developing the layout for the application, be careful to minimize board capacitance and leakage currents around this pin. Traces connected to SRT should be kept as short as possible. Traces carrying high-speed digital signals and traces with large voltage potentials should be routed as far from SRT as possible. Leakage current and stray capacitance (e.g., a scope probe) at this pin could cause errors in the reset timeout period. When evaluating these parts, use clean prototype boards to ensure accurate reset periods.
