TV sound AM-demodulator and  
audio source switch

Product specification  
File under Integrated Circuits, IC02

June 1994

## TV sound AM-demodulator and audio source switch

TDA9830

## FEATURES

- Adjustment free wideband synchronous AM demodulator
- Audio source-mute switch (low noise)
- Audio level according EN50049
- 5 to 8 V power supply or 12 V alternative
- Low power consumption.

## GENERAL DESCRIPTION

The TDA9830, a monolithic integrated circuit, is designed for AM-sound demodulation used in L- and L'-standard. The IC provides an audio source selector and also mute switch.

## QUICK REFERENCE DATA

SYMBOL	PARAMETER	MIN.	TYP.	MAX.	UNIT
V <sub>14</sub>	positive supply voltage	4.5	5.0	8.8	V

## FUNCTIONAL DESCRIPTION

## Sound IF input

The sound IF amplifier consists of three AC-coupled differential amplifier stages each with approximately 20 dB gain. At the output of each stage is a multiplier for gain controlling (→ current distribution gain control). The overall control range is approximately –6 to +60 dB and the frequency response (–3 dB) of the IF amplifier is approximately 6 to 70 MHz. The steepness of gain control is approximately 10 mV/dB.

## IF AGC

The automatic gain control voltage to maintain the AM demodulator output signal at a constant level is generated by a mean level detector. This AGC-detector charges and discharges the capacitor at pin 3 controlled by the output signal of the AM-demodulator compared to an internal reference voltage. The

maximum charge/discharge current is approximately 5  $\mu$ A. This value in combination with the value of the AGC capacitor and the AGC steepness determines the lower cut-off audio frequency and the THD-figure at low modulation frequency of the whole AM-demodulator. Therefore a large time constant has to be chosen which leads to slow AGC reaction at IF level change. To speed up the AGC in case of IF signal jump from low to high level, there is an additional comparator built in, which can provide additional discharge current from the AGC capacitor up to 5 mA in a case of overloading the AM demodulator by the internal IF signal.

## AM-demodulator

The IF amplifier output signal is fed to a limiting amplifier (two stages) and to a multiplier circuit. However the limiter output signal (which is not any more AM modulated) is also fed to the multiplier, which provides AM

demodulation (in phase demodulation). After lowpass filtering ( $f_g \approx 400$  kHz) for carrier rejection and buffering, the demodulator output signal is present at pin 6. The AM demodulator operates over a wide frequency range, so that in combination with the frequency response of the IF amplifier applications in a frequency range from approximately 6 MHz up to 70 MHz are possible.

## Audio switch

This circuit is an operational amplifier with three input stages and internal feedback network determining gain (0 dB) and frequency response ( $f_g \approx 700$  kHz). Two of the input stages are connected to pin 7 and pin 9, the third input stage to an internal reference voltage. Controlled by the switching pins 10 and 12, one of the three input stages can be activated and a choice made between two different AF signals or mute state. The selected signal is present at

TV sound AM-demodulator and audio source switch

TDA9830

pin 8. The decoupling capacitors at the input pins are needed, because the internally generated bias voltage for the input stages must not be influenced by the application in order to avoid DC-plop in case of switching.

The AM demodulator output is designed to provide almost the same DC voltage as the input bias voltage of the audio switch. But there may be spread between both voltages. Therefore it is possible to connect pin 6 directly to pin 7 (without a decoupling capacitor), but in this event the DC-plop for switching can increase up to 100 mV.

**Reference circuit**

This circuit is a band gap stabilizer in combination with a voltage regulation amplifier, which provides an internal reference voltage of about 3.6 V nearly independent from supply voltage and temperature. This reference voltage is filtered by the capacitor at pin 4 in order to reduce noise. It is used as a reference to generate all important voltages and currents of the circuit.

For application in 12 V power supply concepts, there is an internal voltage divider in combination with a

Darlington transistor in order to reduce the supply voltage for all IC function blocks to approximately 6 V. This is necessary because of use of modern high frequency IC technology, where most of the used integrated components are only allowed to operate at maximum 9 V supply voltage.

**LIMITING VALUES**

In accordance with the Absolute Maximum Rating System (IEC134).

SYMBOL	PARAMETER	MIN.	MAX.	UNIT
V <sub>14-13</sub>	supply voltage V <sub>P1</sub>	-0.5	+8.9	V
V <sub>11-13</sub>	supply voltage V <sub>P2</sub>	-0.5	+13.3	V
V <sub>10, 12-13</sub>	switching voltage	-0.5	V <sub>P</sub> + 0.5	V
T <sub>amb</sub>	operating ambient temperature	0	+70	°C
T <sub>stg</sub>	storage temperature	-25	+150	°C

**Note to the limiting values**

1. To avoid an inadmissible increase of ambient temperature, it is not allowed to short-circuit pin 11 for more than 10 seconds to ground.

**THERMAL RESISTANCE**

SYMBOL	PARAMETER	THERMAL RESISTANCE
R <sub>th j-a</sub>	from junction to ambient in free air SOT38 SOT109	74 K/W 100 K/W

$V_{8-13}$	DC-plop at AF output pin with switching from internal to external audio signal or to mute-state or vice-versa	note 5	–	5	10	mV
$R_8$	output resistance		70	100	150	$\Omega$
<b>Ripple rejection</b> note 6						
RR	AF signal output: $\alpha_{RR} = V_{\text{ripple on } V_P} / V_{\text{ripple on } V_{\text{out}}}$		26	30	–	dB
	AF signal output with AF signal from external source		40	44	–	dB

**Notes to the characteristics**

- In the power supply voltage range  $V_{P1} = 5.0$  V up to 8.0 V the performance will not change essentially.  
With power supply from  $V_{P2} = 12.0$  V the performance will be comparable with the performance at  $V_{P1} = 5.0$  V up to 8.0 V.  
The unused power supply pin must be not connected.
- Start of gain control (low IF input signal) at –3 dB AF signal reduction at pin 6.
- End of gain control (high IF input signal) at +1 dB AF signal expansion at pin 6.
- This state is also valid for pin left open-circuit.
- If a DC-plop of about maximum 100 mV is acceptable when switching from internal to external audio-signal or from internal to mute state or vice versa, the capacitor between pin 6 and 7 can be omitted and pin 6 can be connected to pin 7.
- Measured with  $V_{\text{ripple}} = 200$  mV<sub>(p-p)</sub> at 70 Hz superimposed on supply voltage  $V_P$ .
- Dependent on value of AGC capacitor.

## TV sound AM-demodulator and audio source switch

TDA9830

**SOLDERING****Introduction**

There is no soldering method that is ideal for all IC packages. Wave soldering is often preferred when through-hole and surface mounted components are mixed on one printed-circuit board. However, wave soldering is not always suitable for surface mounted ICs, or for printed-circuits with high population densities. In these situations reflow soldering is often used.

This text gives a very brief insight to a complex technology. A more in-depth account of soldering ICs can be found in our *"IC Package Databook"* (order code 9398 652 90011).

**DIP****SOLDERING BY DIPPING OR BY WAVE**

The maximum permissible temperature of the solder is 260 °C; solder at this temperature must not be in contact with the joint for more than 5 seconds. The total contact time of successive solder waves must not exceed 5 seconds.

The device may be mounted up to the seating plane, but the temperature of the plastic body must not exceed the specified maximum storage temperature ( $T_{stg\ max}$ ). If the printed-circuit board has been pre-heated, forced cooling may be necessary immediately after soldering to keep the temperature within the permissible limit.

**REPAIRING SOLDERED JOINTS**

Apply a low voltage soldering iron (less than 24 V) to the lead(s) of the package, below the seating plane or not more than 2 mm above it. If the temperature of the soldering iron bit is less than 300 °C it may remain in contact for up to 10 seconds. If the bit temperature is between 300 and 400 °C, contact may be up to 5 seconds.

**SO****REFLOW SOLDERING**

Reflow soldering techniques are suitable for all SO packages.

Reflow soldering requires solder paste (a suspension of fine solder particles, flux and binding agent) to be applied

to the printed-circuit board by screen printing, stencilling or pressure-syringe dispensing before package placement.

Several techniques exist for reflowing; for example, thermal conduction by heated belt. Dwell times vary between 50 and 300 seconds depending on heating method. Typical reflow temperatures range from 215 to 250 °C.

Preheating is necessary to dry the paste and evaporate the binding agent. Preheating duration: 45 minutes at 45 °C.

**WAVE SOLDERING**

Wave soldering techniques can be used for all SO packages if the following conditions are observed:

- A double-wave (a turbulent wave with high upward pressure followed by a smooth laminar wave) soldering technique should be used.
- The longitudinal axis of the package footprint must be parallel to the solder flow.
- The package footprint must incorporate solder thieves at the downstream end.

During placement and before soldering, the package must be fixed with a droplet of adhesive. The adhesive can be applied by screen printing, pin transfer or syringe dispensing. The package can be soldered after the adhesive is cured.

Maximum permissible solder temperature is 260 °C, and maximum duration of package immersion in solder is 10 seconds, if cooled to less than 150 °C within 6 seconds. Typical dwell time is 4 seconds at 250 °C.

A mildly-activated flux will eliminate the need for removal of corrosive residues in most applications.

**REPAIRING SOLDERED JOINTS**

Fix the component by first soldering two diagonally-opposite end leads. Use only a low voltage soldering iron (less than 24 V) applied to the flat part of the lead. Contact time must be limited to 10 seconds at up to 300 °C. When using a dedicated tool, all other leads can be soldered in one operation within 2 to 5 seconds between 270 and 320 °C.

**DEFINITIONS**

<b>Data sheet status</b>	
Objective specification	This data sheet contains target or goal specifications for product development.
Preliminary specification	This data sheet contains preliminary data; supplementary data may be published later.
Product specification	This data sheet contains final product specifications.
<b>Limiting values</b>	
Limiting values given are in accordance with the Absolute Maximum Rating System (IEC 134). Stress above one or more of the limiting values may cause permanent damage to the device. These are stress ratings only and operation of the device at these or at any other conditions above those given in the Characteristics sections of the specification is not implied. Exposure to limiting values for extended periods may affect device reliability.	
<b>Application information</b>	
Where application information is given, it is advisory and does not form part of the specification.	

**LIFE SUPPORT APPLICATIONS**

These products are not designed for use in life support appliances, devices, or systems where malfunction of these products can reasonably be expected to result in personal injury. Philips customers using or selling these products for use in such applications do so at their own risk and agree to fully indemnify Philips for any damages resulting from such improper use or sale.
