Speech and loudspeaker amplifier IC with auxiliary inputs/outputs and analog multiplexer

TEA1097

FEATURES

Line interface

- Low DC line voltage
- Voltage regulator with adjustable DC voltage
- Symmetrical high-impedance inputs (70 k Ω) for dynamic, magnetic or electric microphones
- Dual Tone Multi-Frequency (DTMF) input with confidence tone on earphone and/or loudspeaker
- Receive amplifier for dynamic, magnetic or piezo-electric earpieces (with externally adjustable gain)
- Automatic Gain Control (AGC) for true line loss compensation.

Supplies

- Provides a strong 3.35 V regulated supply for microcontroller or dialler
- Provides filtered power supply, optimized according to line current and compatible with external voltage or current sources
- Filtered 2 V power supply output for electret microphone
- Compatible with a ringer mode
- Power-Down (\overline{PD}) logic input for power-down.

Loudspeaker amplifier

- Single-ended rail-to-rail output
- Externally adjustable gain
- Dynamic limiter to prevent distortion
- Logarithmic volume control via linear potentiometer.

Auxiliary interfaces

- Asymmetrical high-impedance input for electret microphone.

- General purpose auxiliary output for transmit and receive
- Auxiliary transmit input with high signal level capability dedicated to line transmission
- Auxiliary receive input with high signal level capability
- Integrated multiplexer for channels selection.

APPLICATIONS

- Telephone answering machines
- Telephones with digital handsfree
- Line powered telephone sets
- Cordless telephones
- Fax machines.

GENERAL DESCRIPTION

The TEA1097 is an analog bipolar circuit dedicated for telephone applications. It includes a line interface, handset microphone and earpiece amplifiers, base microphone and loudspeaker amplifiers, some specific auxiliary Inputs/Outputs (I/Os) and an analog multiplexer to enable the right transmit and/or receive channels. The multiplexer is controlled by a logic circuitry decoding four logic inputs provided by a microcontroller. Twelve different application modes have been defined and can be accessed by selecting the right logic inputs.

This IC can be supplied by the line and/or by the mains if available (in a cordless telephone or a telephone answering machine for example). It provides a 3.35 V supply for a microcontroller or dialler and a 2 V filtered voltage supply for electret microphones. The IC is designed to facilitate the use of the loudspeaker amplifier during ringing phase.

FUNCTIONAL DESCRIPTION

All data given in this chapter are typical values, except when otherwise specified.

Supplies

LINE INTERFACE AND INTERNAL SUPPLY (PINS LN, SLPE, REG AND V_{BB})

The supply for the TEA1097 and its peripherals is obtained from the line. The IC generates a stabilized reference voltage (V_{ref}) between pins SLPE and GND. This reference voltage is equal to 3.7 V for line currents lower than 18 mA. It then increases linearly with the line current and reaches the value of 6.1 V for line currents higher than 45 mA. For line currents below 9 mA, the internal reference voltage generating V_{ref} is automatically adjusted to a lower value. This is the so-called low voltage area and the TEA1097 has limited performances in this area (see Section “Low voltage behaviour”). This reference voltage is temperature compensated.

The voltage between pins SLPE and REG is used by the internal regulator to generate the stabilized reference voltage and is decoupled by means of a capacitor between pins LN and REG.

This capacitor converted into an equivalent inductance realizes the set impedance conversion from its DC value (R_{SLPE}) to its AC value (done by an external impedance).

The IC regulates the line voltage at pin LN and it can be calculated as follows:

$$V_{LN} = V_{ref} + R_{SLPE} \times I_{SLPE}$$

$$I_{SLPE} = I_{line} - I^x$$

where:

I_{line} = line current

I^x = current consumed on pin LN (approximately a few μA)

I_{SLPE} = current flowing through the R_{SLPE} resistor.

Speech and loudspeaker amplifier IC with auxiliary inputs/outputs and analog multiplexer

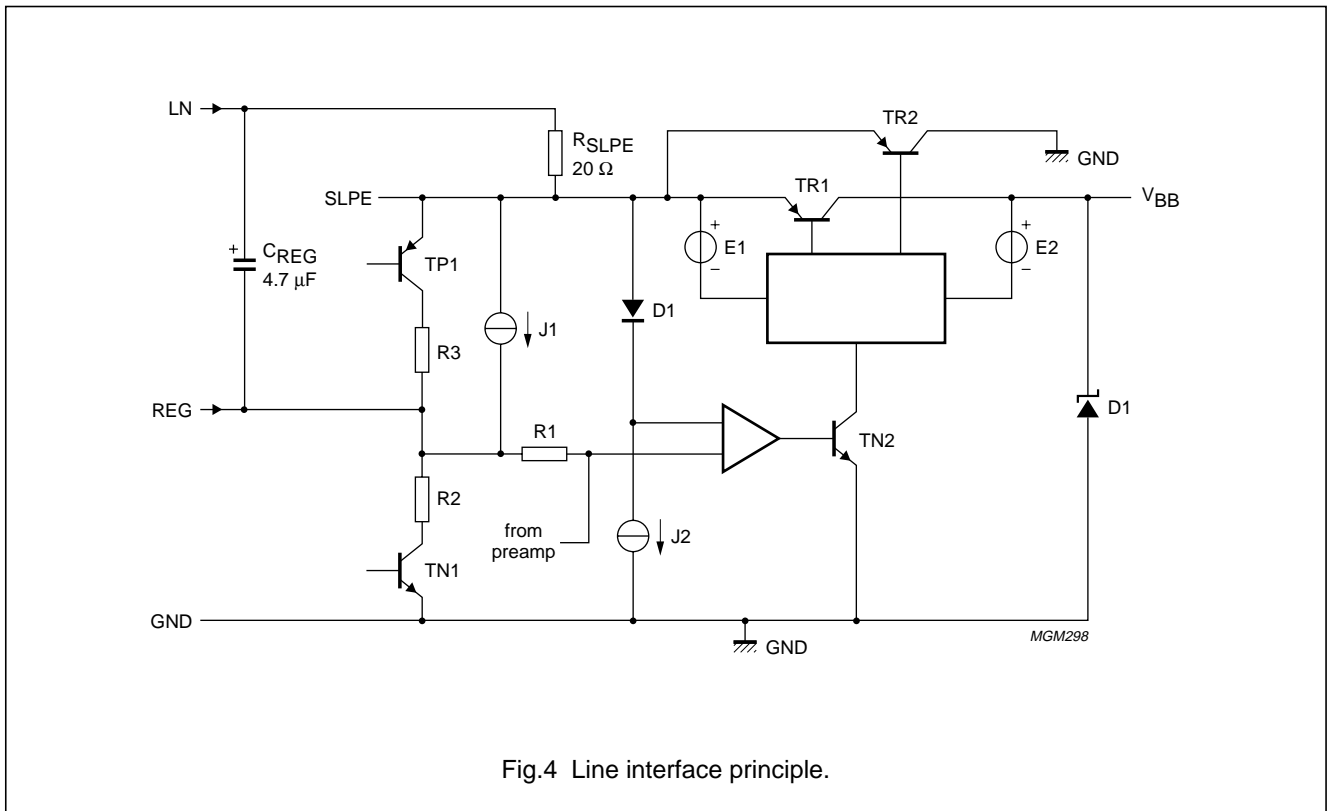

TEA1097

The preferred value for R_{SLPE} is $20\ \Omega$. Changing this value will affect more than the DC characteristics; it also influences the transmit gains to the line, the gain control characteristic, the sidetone level and the maximum output swing on the line.

As can be seen from Fig.4, the internal circuitry is supplied by pin V_{BB} , which is a strong supply point combined with the line interface. The line current is flowing through the R_{SLPE} resistor and is sunk by the V_{BB} voltage stabilizer, becoming available for a loudspeaker amplifier or any peripheral IC. Its voltage is equal to 3.0 V for line currents lower than 18 mA. It then increases linearly with the line current and reaches the value of 5.3 V for line currents greater than 45 mA. It is temperature compensated.

The aim of the current switch TR1 and TR2 is to reduce distortion of large AC line signals. Current I_{SLPE} is supplied to V_{BB} via TR1 when the voltage on SLPE is greater than $V_{BB} + 0.25\text{ V}$. When the voltage on SLPE is lower than this value, the current I_{SLPE} is shunted to GND via TR2.

The reference voltage V_{ref} can be increased by connecting an external resistor between pins REG and SLPE. For large line currents, this increase can slightly affect some dynamic performances such as maximum signal level on the line for 2% THD. The voltage on pin V_{BB} is not affected by this external resistor. See Fig.5 for the main DC voltages.

Speech and loudspeaker amplifier IC with auxiliary inputs/outputs and analog multiplexer

TEA1097

Fig.5 Main DC voltages as a function of line current.

EXTERNAL SUPPLY (PINS ESI AND V_{BB})

The TEA1097 can be supplied by the line as well as by external power sources (voltage or current sources) that must be connected to pin ESI.

The IC will choose which supply to use according to the voltage it can provide. A voltage supply on ESI is efficient only if its value is greater than the working voltage of the internal V_{BB} voltage stabilizer. Otherwise the IC continues to be line powered. The current consumed on this source is at least equal to the internal consumption. It depends on the voltage difference between the value forced on ESI and the working voltage of the internal stabilizer.

The current required increases with the voltage difference to manage. The excess current compared to the internal consumption becomes then available for other purposes such as supplying a loudspeaker amplifier. The voltage source should not exceed 6 V. If the value of the external voltage source can be lower than the working voltage of the internal stabilizer, an external diode is required to avoid reverse current flowing into the external power supply.

In case of current source, the voltage on V_{BB} and ESI depends on the current available. It is internally limited to 6.6 V. The current source should not exceed 140 mA.

V_{DD} SUPPLY FOR MICROCONTROLLERS (PIN V_{DD})

The voltage on V_{DD} supply point follows the voltage on V_{BB} with a difference equal to 250 mV (typ.) and is internally limited to 3.35 V. This voltage is temperature compensated. This supply point can provide a current up to 3 mA (typ.). Its internal consumption stays low (a few 10 nA) as long as V_{DD} does not exceed 1.5 V (see Fig.6).

An external voltage can be connected on V_{DD} with limited extra consumption on V_{DD} (typically 100 μ A). This voltage source should not be lower than 3.5 V and higher than 6 V.

V_{BB} and V_{DD} can supply external circuits in the limits of currents provided either from the line or from pin ESI, taking into account the internal current consumption.

Speech and loudspeaker amplifier IC with auxiliary inputs/outputs and analog multiplexer

TEA1097

Fig.6 Current consumption on V_{DD}.

SUPPLY FOR MICROPHONE (PINS MICS AND GNCTX)

The MICS output can be used as a supply for an electret microphone. Its voltage is equal to 2 V; it can source current up to 1 mA and has an output impedance equal to 200 Ω.

LOW VOLTAGE BEHAVIOUR

For line currents below 9 mA, the reference voltage is automatically adjusted to a lower value; the V_{BB} voltage follows the SLPE voltage with 250 mV difference. The excess current available for other purposes than DC biasing of the IC becomes small. In this low voltage area, the IC has limited performances.

When the V_{BB} voltage reaches 2.7 V, the V_{BB} detector of the receive dynamic limiter on pin LSAO acts continuously, discharging the capacitor at pin DLC. In the DC condition, the loudspeaker is automatically disabled below this voltage.

When V_{BB} becomes lower than 2.5 V, the TEA1097 is forced in a low voltage mode whatever the levels on the logic inputs are. It is a speech mode with reduced performances only enabling the microphone channel (between the MIC inputs and LN) and the earpiece amplifier. These two channels are able to deliver signals for line currents as small as 3 mA. The HFC input is tied to GND sinking a current equal to 300 μA (typ.).

POWER-DOWN MODE (PINS $\overline{\text{PD}}$ AND AUXC)

To reduce current consumption during dialling or register recall (flash), the TEA1097 is provided with a power-down input ($\overline{\text{PD}}$). When the voltage on pins $\overline{\text{PD}}$ and AUXC is LOW, the current consumption from V_{BB} and V_{DD} is reduced to 460 μA (typ.). Therefore a capacitor of 470 μF connected to pin V_{BB} is sufficient to power the TEA1097 during pulse dialling or flash. The $\overline{\text{PD}}$ input has a pull-up structure, while AUXC has a pull-down structure. In this mode, the capacitor C_{REG} is internally disconnected.

Speech and loudspeaker amplifier IC with auxiliary inputs/outputs and analog multiplexer

TEA1097

RINGER MODE (PINS ESI, V_{BB} , AUXC AND \overline{PD})

The TEA1097 is designed to be activated during the ringing phase. The loudspeaker amplifier can be used for the melody signal. The IC must be powered by an external supply on pin ESI, while applying a HIGH level on the logic input AUXC and a LOW level on the \overline{PD} input. Only the HFRX input and the LSAO output are activated, in order to limit the current consumption. Some dynamic limiting is provided to prevent V_{BB} from being discharged below 2.7 V.

Transmit channels (pins MIC+, MIC-, DTMF, TXAUX and LN)

HANDSET MICROPHONE AMPLIFIER (PINS MIC+, MIC- AND LN)

The TEA1097 has symmetrical microphone inputs. The input impedance between MIC+ and MIC- is 70 k Ω (typ.). The voltage gain between pins MIC+, MIC- and LN is set to 44.3 dB. Without limitation from the output, the microphone input stage can accommodate signals up to 18 mV (RMS) at room temperature for 2% of THD. The microphone inputs are biased at one diode voltage.

Automatic gain control is provided for line loss compensation.

DTMF AMPLIFIER (PINS DTMF, LN AND RECO)

The TEA1097 has an asymmetrical DTMF input. The input impedance between pin DTMF and GND is 20 k Ω (typ.). The voltage gain between pins DTMF and LN is set to 25.35 dB. Without limitation from the output, the input stage can accommodate signals up to 180 mV (RMS) at room temperature for 2% of THD.

When the DTMF amplifier is enabled, dialling tones may be sent on the line. These tones can be heard in the earpiece or in the loudspeaker at a low level. This is called the confidence tone. The voltage attenuation between pins DTMF and RECO is typically equal to -16.5 dB.

The DC biasing of this input is 0 V.

The automatic gain control has no effect on these channels.

AUXILIARY TRANSMIT AMPLIFIER (PINS TXAUX AND LN)

The TEA1097 has an asymmetrical auxiliary input TXAUX. The input impedance between pins TXAUX and GND is 20 k Ω (typ.). The voltage gain between pins TXAUX and LN is set to 12.5 dB. Without limitation from the output, the input stage can accommodate signals up to 1.2 V (RMS) at room temperature for 2% of THD. The TXAUX input is biased at two diodes voltage.

Automatic gain control is provided for line loss compensation.

MICROPHONE MONITORING ON TXOUT (PINS MIC+, MIC- AND TXOUT)

The voltage gain between the microphone inputs MIC+, MIC- and the output TXOUT is set to 49.8 dB. This channel gives an image of the signal sent on the line while speaking in the handset microphone. Using external circuitry, this signal can be used for several purposes such as sending dynamic limiting or anti-howling in a listening-in application. The TXOUT output is biased at two diodes voltage.

The automatic gain control has no effect on these channels.

Receive channels (pins IR, RAUX, RECO, GARX and QR)

RX AMPLIFIER (PINS IR AND RECO)

The receive amplifier has one input IR which is referred to the line. The input impedance between pins IR and LN is 20 k Ω (typ.) and the DC biasing between these pins is equal to one diode voltage. The gain between pins IR (referenced to LN) and RECO is typically equal to 29.7 dB. Without limitation from the output, the input stage can accommodate signals up to 50 mV (RMS) at room temperature for 2% of THD.

This receive amplifier has a rail-to-rail output RECO, which is designed for use with high-ohmic (real) loads (larger than 5 k Ω). This output is biased at two diodes voltage.

Automatic gain control is provided for line loss compensation.

Speech and loudspeaker amplifier IC with auxiliary inputs/outputs and analog multiplexer

TEA1097

EARPIECE AMPLIFIER (PINS GARX AND QR)

The earpiece amplifier is an operational amplifier having its output (QR) and its inverting input (GARX) available. Its input signal comes, via a decoupling capacitor, from the receive RECO output. It is used in combination with two resistors to get the required gain or attenuation compared to the receive gain. It can be chosen between -3 and $+15$ dB.

Two external capacitors C_{GAR} (connected between pins GARX and QR) and C_{GARS} (connected between pins GARX and GND) ensure stability. The C_{GAR} capacitor provides a first-order low-pass filter. The cut-off frequency corresponds to the time constant $C_{GAR} \times R_{e2}$. The relationship $C_{GARS} \geq 10 \times C_{GAR}$ must be fulfilled.

The earpiece amplifier has a rail-to-rail output QR, biased at two diodes voltage. It is designed for use with low-ohmic (real) loads (150Ω) or capacitive loads (100 nF in series with 100Ω).

When the amplifier is turned off, the signal present on the earpiece is equal to the ratio between the load on QR and $R_{e1} + R_{e2}$.

AUXILIARY RECEIVE AMPLIFIER (PINS RAUX AND RECO)

The auxiliary receive amplifier has an asymmetrical input RAUX; it uses the RECO output. Its input impedance between pins RAUX and GND is typically equal to 20 k Ω . The voltage gain between pins RAUX and RECO is equal to -2.4 dB. Without any limitation from the output, the input stage can accommodate signals up to 0.95 V (RMS) at room temperature for 2% of THD.

This auxiliary amplifier has a rail-to-rail output RECO, which is designed for use with high ohmic (real) loads (larger than 5 k Ω). This output is biased at two diodes voltage.

The automatic gain control has no effect on this channel.

Auxiliary amplifiers using AUXO (pins MIC+, MIC-, HFTX, IR and AUXO)

The TEA1097 has an auxiliary output AUXO, biased at two diodes voltage. This output stage is a rail-to-rail one, designed for use with high-ohmic (real) loads (larger than 5 k Ω). The AUXO output amplifier is used in three different channels, two transmit channels and one receive channel.

AUXILIARY AMPLIFIERS USING THE MICROPHONE INPUTS (PINS MIC+, MIC- AND AUXO)

The auxiliary transmit amplifier using the microphone MIC+ and MIC- inputs has a gain of 25.5 dB referenced to AUXO. Without limitation from the output, the input stage can accommodate signals up to 16 mV (RMS) at room temperature for 2% of THD.

The automatic gain control has no effect on this channel.

AUXILIARY AMPLIFIERS USING HFTX (PINS HFTX AND AUXO)

The auxiliary transmit amplifier using the HFTX input has a gain of 15.2 dB referenced to AUXO.

The automatic gain control has no effect on this channel.

RX AMPLIFIER USING IR (PINS IR AND AUXO)

The auxiliary receive amplifier uses pin IR as input. The input is referenced to pin LN and the DC biasing between these two pins is one diode voltage. The voltage gain between the input IR (referenced to LN) and the output AUXO is typically equal to 32.8 dB, which compensates typically the attenuation provided by the anti-sidetone network.

Automatic gain control is provided for line loss compensation.

Automatic gain control (pin AGC)

The TEA1097 performs automatic line loss compensation, which fits well with the true line attenuation. The automatic gain control varies the gain of some transmit and receive amplifiers in accordance with the DC line current.

The control range is 6.45 dB for $G_{V(MIC-LN)}$, $G_{V(IR-RECO)}$ and $G_{V(IR-AUXO)}$ and 6.8 dB for $G_{V(TXAUX-LN)}$, which corresponds approximately to a line length of 5.5 km for a 0.5 mm twisted-pair copper cable.

To enable this gain control, the pin AGC must be shorted to pin LN. The start current for compensation corresponds to a line current equal to typically 23 mA and the stop current to 57 mA. The start current can be increased by connecting an external resistor between pins AGC and LN. It can be increased to 40 mA (using a resistor typically equal to 80 k Ω). The start and stop current will be maintained in a ratio equal to 2.5 . By leaving the AGC pin open-circuit, the gain control is disabled and no line loss compensation is performed.

Speech and loudspeaker amplifier IC with auxiliary inputs/outputs and analog multiplexer

TEA1097

Base microphone channel (pins TXIN, GATX, TXOUT and GNDTX) see Fig.7

The TEA1097 has an asymmetrical base microphone input TXIN with an input resistance of 20 kΩ. The DC biasing of the input is 0 V.

The output TXOUT is biased at two diodes voltage and has a current capability equal to 20 μA (RMS). The gain of the microphone amplifier (from pins TXIN to TXOUT) can be adjusted from 0 to 31 dB to suit specific application requirements.

The gain is proportional to the value of R_{GATX} and equals 14.85 dB with R_{GATX} = 30.1 kΩ. Without limitation from the output, the microphone input stage can accommodate signals up to 18 mV (RMS) at room temperature for 2% of THD.

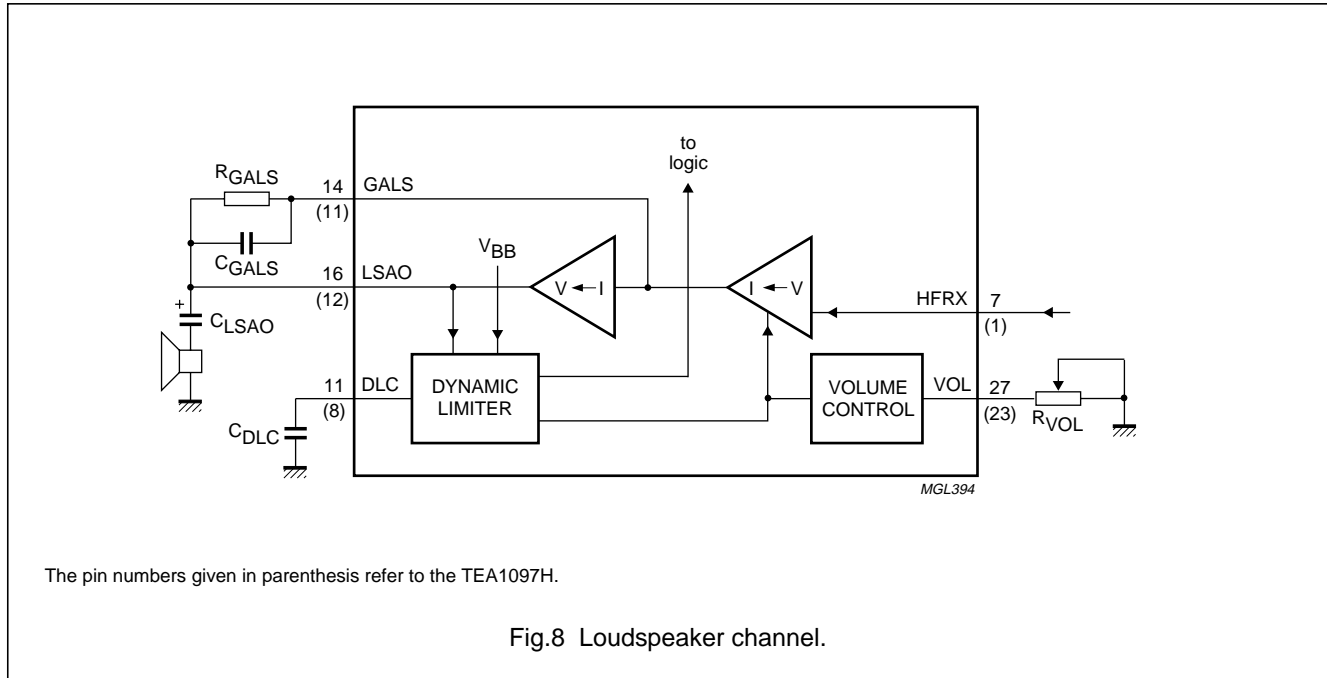

A capacitor can be connected in parallel with R_{GATX} to provide a 1st-order low-pass filter.

Speech and loudspeaker amplifier IC with auxiliary inputs/outputs and analog multiplexer

TEA1097

Loudspeaker channel

LOUDSPEAKER AMPLIFIER: PINS HFRX, GALS AND LSAO

The TEA1097 has an asymmetrical input for the loudspeaker amplifier with an input resistance of 20 k Ω between pins HFRX and GND. It is biased at two diodes voltage. The input stage can accommodate signals up to 580 mV (RMS) at room temperature for 2% of THD.

The rail-to-rail output stage is designed to power a loudspeaker down to 8 Ω connected as a single-ended load (between pins LSAO and GND). When the circuit is externally supplied, the maximum output power is equal to 280 mW (typ.) for 6 V applied to pin ESI.

The gain of the loudspeaker amplifier can be adjusted from 0 to 35 dB to suit specific application requirements. The gain from HFRX to LSAO is proportional to the value of R_{GALS} and equals 28 dB with $R_{GALS} = 255$ k Ω . A capacitor connected in parallel with R_{GALS} is recommended and provides a first-order low-pass filter.

VOLUME CONTROL (PIN VOL)

The loudspeaker amplifier gain can be adjusted with the potentiometer R_{VOL} . A linear potentiometer can be used to obtain logarithmic control of the gain at the loudspeaker amplifier. Each 1.9 k Ω increase of R_{VOL} results in a gain loss of 3 dB.

DYNAMIC LIMITER (PIN DLC)

The dynamic limiter of the TEA1097 prevents clipping of the loudspeaker output stage and protects the operation of the circuit when the supply voltage at V_{BB} falls below 2.7 V.

Hard clipping of the loudspeaker output stage is prevented by rapidly reducing the gain when the output stage starts to saturate. The time in which gain reduction is effected (clipping attack time) is approximately a few milliseconds. The circuit stays in the reduced gain mode until the peaks of the loudspeaker signals no longer cause saturation. The gain of the loudspeaker amplifier then returns to its normal value within the clipping release time (typically 100 ms). Both attack and release times are proportional to the value of the capacitor C_{DLC} . The total harmonic distortion of the loudspeaker output stage, in reduced gain mode, stays below 1% up to 10 dB (min.) of input voltage overdrive [providing V_{HFRX} is below 580 mV (RMS)].

When the supply voltage drops below an internal threshold voltage of 2.7 V, the gain of the loudspeaker amplifier is rapidly reduced (approximately 1 ms). When the supply voltage exceeds 2.7 V, the gain of the loudspeaker amplifier is increased again. By forcing a level lower than 0.2 V on pin DLC, the loudspeaker amplifier is muted.

SOLDERING

Introduction to soldering surface mount packages

This text gives a very brief insight to a complex technology. A more in-depth account of soldering ICs can be found in our *"Data Handbook IC26; Integrated Circuit Packages"* (document order number 9398 652 90011).

There is no soldering method that is ideal for all surface mount IC packages. Wave soldering is not always suitable for surface mount ICs, or for printed-circuit boards with high population densities. In these situations reflow soldering is often used.

Reflow soldering

Reflow soldering requires solder paste (a suspension of fine solder particles, flux and binding agent) to be applied to the printed-circuit board by screen printing, stencilling or pressure-syringe dispensing before package placement.

Several methods exist for reflowing; for example, infrared/convection heating in a conveyor type oven. Throughput times (preheating, soldering and cooling) vary between 100 and 200 seconds depending on heating method.

Typical reflow peak temperatures range from 215 to 250 °C. The top-surface temperature of the packages should preferably be kept below 230 °C.

Wave soldering

Conventional single wave soldering is not recommended for surface mount devices (SMDs) or printed-circuit boards with a high component density, as solder bridging and non-wetting can present major problems.

To overcome these problems the double-wave soldering method was specifically developed.

If wave soldering is used the following conditions must be observed for optimal results:

- Use a double-wave soldering method comprising a turbulent wave with high upward pressure followed by a smooth laminar wave.
- For packages with leads on two sides and a pitch (e):
 - larger than or equal to 1.27 mm, the footprint longitudinal axis is **preferred** to be parallel to the transport direction of the printed-circuit board;
 - smaller than 1.27 mm, the footprint longitudinal axis **must** be parallel to the transport direction of the printed-circuit board.

The footprint must incorporate solder thieves at the downstream end.

- For packages with leads on four sides, the footprint must be placed at a 45° angle to the transport direction of the printed-circuit board. The footprint must incorporate solder thieves downstream and at the side corners.

During placement and before soldering, the package must be fixed with a droplet of adhesive. The adhesive can be applied by screen printing, pin transfer or syringe dispensing. The package can be soldered after the adhesive is cured.

Typical dwell time is 4 seconds at 250 °C. A mildly-activated flux will eliminate the need for removal of corrosive residues in most applications.

Manual soldering

Fix the component by first soldering two diagonally-opposite end leads. Use a low voltage (24 V or less) soldering iron applied to the flat part of the lead. Contact time must be limited to 10 seconds at up to 300 °C.

When using a dedicated tool, all other leads can be soldered in one operation within 2 to 5 seconds between 270 and 320 °C.

Speech and loudspeaker amplifier IC with auxiliary inputs/outputs and analog multiplexer

TEA1097

Suitability of surface mount IC packages for wave and reflow soldering methods

PACKAGE	SOLDERING METHOD	
	WAVE	REFLOW ⁽¹⁾
BGA, SQFP	not suitable	suitable
HLQFP, HSQFP, HSOP, HTSSOP, SMS	not suitable ⁽²⁾	suitable
PLCC ⁽³⁾ , SO, SOJ	suitable	suitable
LQFP, QFP, TQFP	not recommended ⁽³⁾⁽⁴⁾	suitable
SSOP, TSSOP, VSO	not recommended ⁽⁵⁾	suitable

Notes

- All surface mount (SMD) packages are moisture sensitive. Depending upon the moisture content, the maximum temperature (with respect to time) and body size of the package, there is a risk that internal or external package cracks may occur due to vaporization of the moisture in them (the so called popcorn effect). For details, refer to the Drypack information in the "Data Handbook IC26; Integrated Circuit Packages; Section: Packing Methods".
- These packages are not suitable for wave soldering as a solder joint between the printed-circuit board and heatsink (at bottom version) can not be achieved, and as solder may stick to the heatsink (on top version).
- If wave soldering is considered, then the package must be placed at a 45° angle to the solder wave direction. The package footprint must incorporate solder thieves downstream and at the side corners.
- Wave soldering is only suitable for LQFP, TQFP and QFP packages with a pitch (e) equal to or larger than 0.8 mm; it is definitely not suitable for packages with a pitch (e) equal to or smaller than 0.65 mm.
- Wave soldering is only suitable for SSOP and TSSOP packages with a pitch (e) equal to or larger than 0.65 mm; it is definitely not suitable for packages with a pitch (e) equal to or smaller than 0.5 mm.

DEFINITIONS

Data sheet status	
Objective specification	This data sheet contains target or goal specifications for product development.
Preliminary specification	This data sheet contains preliminary data; supplementary data may be published later.
Product specification	This data sheet contains final product specifications.
Limiting values	
Limiting values given are in accordance with the Absolute Maximum Rating System (IEC 134). Stress above one or more of the limiting values may cause permanent damage to the device. These are stress ratings only and operation of the device at these or at any other conditions above those given in the Characteristics sections of the specification is not implied. Exposure to limiting values for extended periods may affect device reliability.	
Application information	
Where application information is given, it is advisory and does not form part of the specification.	

LIFE SUPPORT APPLICATIONS

These products are not designed for use in life support appliances, devices, or systems where malfunction of these products can reasonably be expected to result in personal injury. Philips customers using or selling these products for use in such applications do so at their own risk and agree to fully indemnify Philips for any damages resulting from such improper use or sale.
