Preface

Thank you very much for making use of Toshiba microcomputer LSIs.
Before use this LSI, refer the section, "Points of Note and Restrictions".
Especially, take care below cautions.

****CAUTION****

How to release the HALT mode

Usually, interrupts can release all halts status. However, the interrupts = (INT0, INT1), which can release the HALT mode may not be able to do so if they are input during the period CPU is shifting to the HALT mode (for about 3 clocks of f_c or f_s) with IDLE1 or STOP mode (IDLE2 is not applicable to this case). (In this case, an interrupt request is kept on hold internally.)

If another interrupt is generated after it has shifted to HALT mode completely, halt status can be released without difficulty. The priority of this interrupt is compare with that of the interrupt kept on hold internally, and the interrupt with higher priority is handled first followed by the other interrupt.

3. Operation

This section describes the functions and basic operational blocks of TMP93CF76/CF77/CW76/CU76/CT76 devices.

See the “7. Points of Concern and Restrictions” for the using notice and restrictions for each block.

3.1 CPU

TMP93CF76/CF77/CW76/CU76/CT76 devices have a built-in high-performance 16-bit CPU (900/L CPU). (For CPU operation, see TLCS-900/L CPU in the previous section).

This section describes CPU functions unique to the TMP93CF76/CF77/CW76/CU76/CT76 that are not described in the previous section.

3.1.1 Reset

To reset the TMP93CF76/CF77/CW76/CU76/CT76, the RESET input must be kept at 0 for at least 10 system clocks. (1.25 μ s at 16 MHz) within the operating voltage range and with a stable oscillation.

When reset is accepted, the CPU sets as follows:

- Program Counter (PC) according to Reset Vector that is stored FFFF00H to FFFF02H.

PC (7:0)	← stored data in location FFFF00H
PC (15:8)	← stored data in location FFFF01H
PC (23:16)	← stored data in location FFFF02H
- Stack pointer (XSP) for system mode to 100H.
- IFF2 to 0 bits of status register to 111. (Sets mask register to interrupt level 7.)
- MAX bit of status register to 1. (Sets to maximum mode)
- Bits RFP2 to 0 of status register to 000. (Sets register banks to 0.)

When reset is released, instruction execution starts from PC (reset vector). CPU internal registers other than the above are not changed.

When reset is accepted, processing for built-in I/Os, ports, and other pins is as follows

- Initializes built-in I/O registers as per specifications.
- Sets port pins (including pins also used as built-in I/Os) to general-purpose input/output port mode.

Note: By resetting, register in the CPU except program counter (PC), status register (SR) and stack pointer (XSP) and the data in internal RAM are not changed.

If any absolute maximum rating is exceeded, a device may break down or its performance may be degraded, causing it to catch fire or explode resulting in injury to the user. Thus, when designing products which include this device, ensure that no absolute maximum rating value will ever be exceeded.

(2) Master SCL output timing

The I2CCR1 <SCK 2:0> are used to select a maximum transfer frequency directed from the SCL pin in the master mode. When rising time of the output clock (t_{RC}) is at least $8/f_c$ [s], a high-level time of the output clock (t_{HC}) is t_{SCL} .

While the SCL line is fixed to low-level by a slave device, the output clock stops.

The first clock (t_{HC} [s]) after restart is $(t_{SCL}/2) \leq t_{HC} \leq t_{SCL}$.

(a) In case of $t_{RC} < (8/f_c)$ [s] $t_{HC} = t_{LC} = t_{SCL}/2$ [s] ($t_{SCL} = 1/f_{SCL}$ [s])

(b) In case of $t_{RC} \geq (8/f_c)$ [s] $t_{HC} = t_{SCL}$ [s], $t_{LC} = t_{SCL}/2$ [s]
