

## Programmable Telephone Audio Processor

### Description

The programmable telephone audio processor U3900BM is a linear integrated circuit for use in feature phones, answering machines, fax machines and cordless phones. It contains the speech circuit, tone-ringer interface with DC/DC converter, sidetone equivalent and ear-protection rectifiers. The circuit is line-powered and contains all components necessary for signal amplification and

adaptation to the line. The U3900BM can also be supplied via an external power supply. An integrated voice switch with loudspeaker amplifier enables hands-free or loud-hearing operation. With an anti-feedback function, acoustical feedback during loudhearing can be reduced significantly. The generated supply voltage is suitable for a wide range of peripheral circuits.

### Features

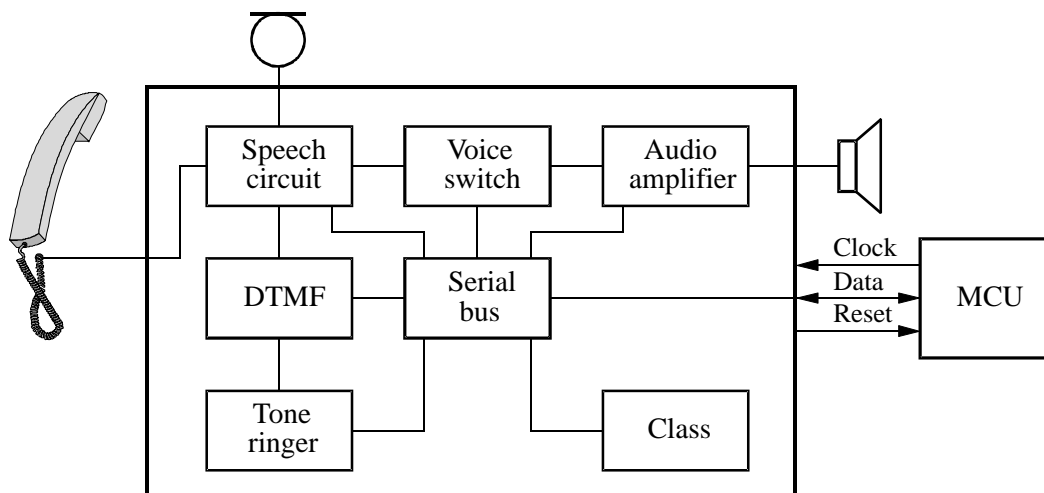

- Speech circuit with anti-clipping
- Tone ringer interface with DC/DC converter
- Speaker amplifier with anti-distortion
- Power-supply management, regulated, unregulated and a special supply for electret microphone
- Voice switch
- CLID + SCWID
- DTMF generator
- Switch matrix
- Line current information
- Fully programmable
- Watchdog

### Benefits

- Savings of one piezoelectric transducer
- Complete system integration of analog signal processing on one chip
- Very few external components
- Highly integrated solution
- Extremely versatile due to full programmability

### Applications

Feature phone, answering machine, fax machine, speaker phone, base station of cordless phone

### Ordering Information

Extended Type Number	Package	Remarks
U3900BM-RFN	SSO44	
U3900BM-RFNG3	SSO44	Taped and reeled

## Pin Description

Figure 1. Pinning

Pin	Symbol	Function
1	SAO1	Positive output of speaker amplifier (single ended and push-pull operation)
2	SAO2	Negative output of speaker amplifier (push-pull only)
3	GND	Ground, reference point for DC- and AC signals
4	VB	Unstabilized supply voltage
5	ES	Input for external supply indication
6	VMPS	Unregulated supply voltage for the microcontroller (via series regulator to VMP)
7	SENSE	Input for sensing the available line current
8	VL	Positive supply-voltage input to the device in speech mode
9	IND	The internal equivalent inductance of the circuit is proportional to the value of the capacitor at this pin. A resistor connected to ground may be used to adjust the DC mask.
10	RECIN	Receive amplifier input

Pin	Symbol	Function
11	ADIN	Input of A/D converter
12	CLI2	CLID input 2
13	CLI1	CLID input 1
14	VRING	Input for ringer supply
15	IMPA	Input for adjusting the ringer input impedance
16	COSC	70-kHz oscillator for ringing power converter
17	SWOUT	Outp. for driving the ext. switching transistor
18	VMP	Regulated output voltage for supplying the μC (typ. 3.3 V/ 6 mA in speech mode)
19	INT	Interrupt line for serial bus
20	BCL	Clock input for serial bus
21	BDA	Data line for serial bus
22	OSCIN	Input for 3.58-MHz oscillator
23	OSCOUT	Clock output for the microcontroller
24	RESET	Reset output for the microcontroller
25	STC	Input for sidetone network
26	STRC	Input for sidetone network
27	STO	Output for connecting the sidetone network
28	AMPB	Input for playback signal of answering machine
29	AMREC	Output for recording signal of answering machine
30	CMIC	Input for cordless telephone
31	CEAR	Output for cordless telephone
32	HFTX	Output for transmit-level detector in intercom mode
33	TLDT	Time constant of transmit-level detector
34	INLDT	Input of transmit-level detector
35	INLDR	Input of receive-level detector
36	TLDR	Time constant of receive-level detector
37	RECO1	Positive output of the receive amplifier, also used for sidetone network
38	RECO2	Negative output of the receive amplifier
39	TXACL	Time-constant adjustment for transmit anti-clipping
40	MIC3	Input of hands-free microphone
41	VMIC	Reference node for microphone amplifier, supply for electret microphone
42	MIC1	Inverting input of symmetrical microphone ampl. with high common-mode rejection ratio
43	MIC2	Non-inverting input of symmetrical microphone amplifier with high common-mode rejection ratio
44	TSACL	Time-constant for speaker amplifier anti-clipping

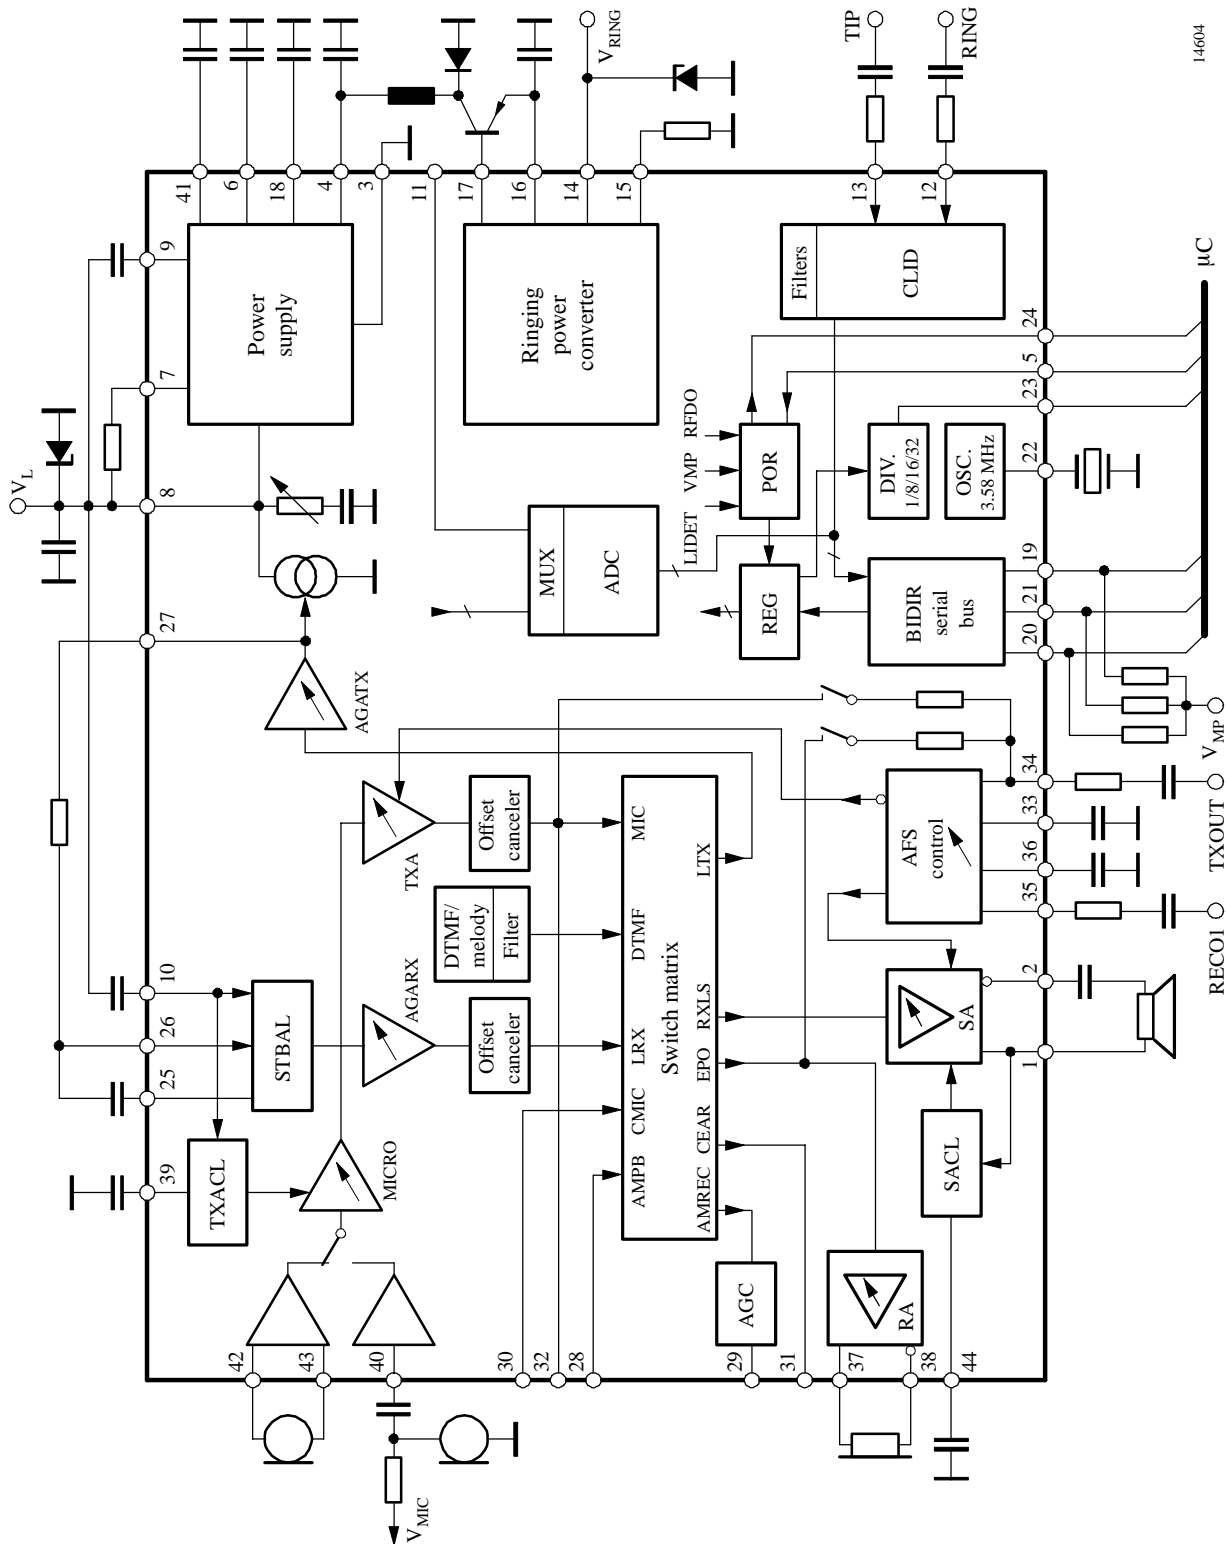

Figure 2. Block diagram

## 2 Class Function

The U3900BM includes a class function **Calling Line Identification (CLID)** for on-hook and **Spontaneous Call Waiting Identifier (SCWID)** for off-hook status.

### 2.1 CLID

CLID is designed to demodulate CCITT V23 and BELL 202 (1200 bauds FSK asynchronous data) and is compatible with both formats without external intervention. It fulfils the CS B14-10W requirements.

The main feature of this part is to provide, for the user, information about the caller before answering the call. The information is a DATA message sent from the **Central Office (CO)** to the CPE during the silent interval, and after the first ringing burst.

#### 2.1.1 Description

On the receive side, the received signal coming from CLI1 and CLI2 first goes to an antialiasing filter after the differential op-amp.

The next section is a bandpass filter composed of an FSK filter composed of a fifth order high-pass followed by a third order low-pass filter. The low-pass and high-pass cut-off frequencies are about 300 Hz and 3400 Hz respectively.

#### 2.1.2 Carrier Detect

The carrier detect provides an indication (to the micro-processor with an interrupt request) of the presence of a signal in the FSK band. It detects a sufficient amplitude signal at the output of the FSK bandpass filter.

Note that signals such as speech or DTMF tones also lie in the FSK frequency band and the carrier detect may be activated by these signals. The signals will be demodulated and presented as DATA. To avoid false DATA detection, a command bit is used to disable the demodulator when no FSK signal is expected.

Four bits are provided to improve carrier detection [CD\_CD <3..0>]. With these bits it is possible to select

a capture window (see the tables next page), and avoid a false detection.

With the use of SCD bit the carrier detect function is improved, because after a normal carrier detection (NCD), a part (10 bits) of the channel seizure is taken in count before alerting the microprocessor.

#### Note:

When the CPE is off hook (SCWID mode) the CO sends FSK data without channel seizure. The mark signal = 80 bits  $\pm$ 10 at 1200 bauds (1300 Hz continuously during 67 ms).

For this case a selected bandpass 1000 Hz to 1700 Hz could be very useful for the carrier detect ...

After the interrupt due to the carrier detect the micro-processor can change the bandpass frequencies according to the FSK band.

- The normal carrier detect guard time is 26.4 ms.
- The improved carrier detect guard time is 34.7 ms.
- The carrier lost guard time is 8.8 ms, in all the cases.

#### 2.1.3 Demodulator

This part is enabled with the carrier detect signal.

The reference signal is at 1700 Hz, (the same frequency for BELL 202 and V23). All the incoming signals are compared to this value to make a digital square wave frequency varying in frequency and in phase as a function of the input frequencies.

#### 2.1.4 Clock Recovery

The process starts at the first low-level bit received from the demodulator. After that the CLOCK is generated for the 10 serial bits (1 bit start, 8 bits data, 1 bit stop). When all the data are received DATA READY is generated. This signal loads the serial data in a parallel buffer.

DATA READY provides an indication (to the micro-processor with an interrupt request) of the presence data byte available.

## 2.1.5 Data Recovery and Buffer

The incoming serial data are stored and sent to the SSB each 10 bits (1 start bit, 8 data, 1 stop bit). When after a start bit 8 data bits and a stop bit are received, an interrupt

is generated, the INT pin will become active, and data ready interrupt bit is set in the status register (bit 3). The received data is available in the CLID DATA register.

Figure 3. Interrupt treatment for SLID DATA register

## 2.1.6 CLID: Logical Part

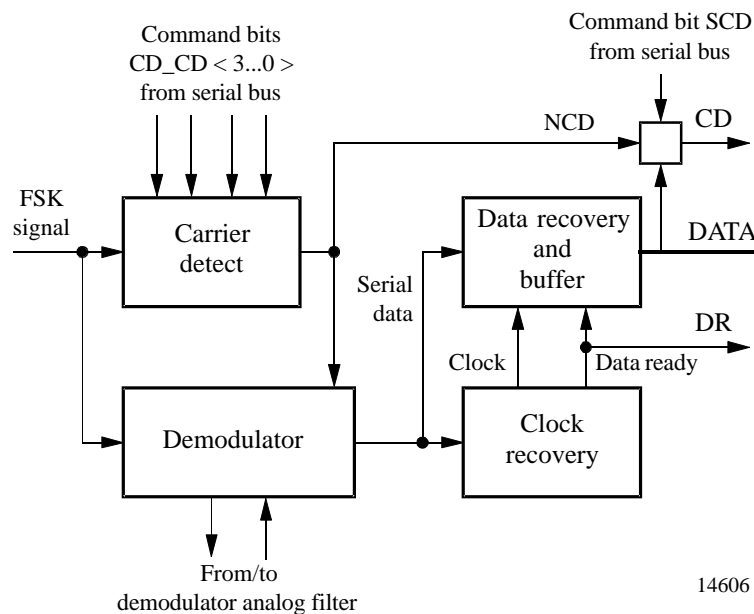

Figure 4. Block diagram for CLID logical part

## 2.1.7 Carrier Detect, Bandpass Frequencies

### Low Frequencies

CD_CD<0>	CD_CD<1>	Value
0	0	290 Hz
1	0	515 Hz
0	1	770 Hz
1	1	1000 Hz

### High Frequencies

CD_CD<2>	CD_CD<3>	Value
0	0	3400 Hz
1	0	3100 Hz
0	1	2665 Hz
1	1	1700 Hz

## 2.1.8 Special Carrier Detect

If SCD = 0 Detect guard time = 26.4 ms

If SCD = 1 Detect guard time = 34.7 ms (26.4 ms + 10 bits of the channel seizure)

Figure 5. Timing diagram for carrier detect in CLID mode

## 2.2 SCWID

Figure 6. Timing diagram for carrier detect in SCWID mode

The Spontaneous Call Waiting Identifier (SCWID) part is designed to meet:

- The Bellcore “Customer Premises Equipment Alerting Signal (CAS)”: TR-NWT-000030 & SR-TSV-002476 specifications.
- The British Telecom “Idle State Tone Alert Signal”: SIN227 & SIN242 specifications.
- The European Telecommunication Standard: ETS300 778-1 & ETS300 778-2 specifications.

### 2.2.1 Overview

SCWID is a feature that allows a subscriber who is already engaged in a telephone call to receive caller ID information about an incoming call.

The European Telecommunication Standard specifies Dual-Tone Alerting Signal (DT-AS) for off-line data transmission (on-hook) and on-line data transmission (off-hook).

The British Telecom caller ID uses a Idle State Tone Alert Signal in on-hook mode.

Bellcore specifies a Dual-Tone Alert Signal called CPE Alerting Signal (CAS) for use in off-hook data transmission. Bellcore states that the CPE should be able to detect the CAS in the presence of near end speech. The CAS detector should also be immune to imitation from near and far end speech.

Note that the term “near end” refers to the end of the telephone connection receiving the caller ID service, “far end” refers to the other end of the connection, the Central Office (CO).

There are two aspects of speech immunity: talk-off and talk-down.

**Talk-off** is the condition where signals are falsely detected because of imitation by speech or music. An imitation can be caused from the far end or the near end.

**Talk-down** is the condition where signals are missed because of interference from speech or music.

A CAS can be talked down only from the near end because the far end has already been muted by the CO.

### 2.2.2 Description

The SCWID part is a complete dual-tone receiver designed to detect the two frequencies 2750 Hz and 2130 Hz dedicated for this alerting function. An output interrupt is provided to the microprocessor when detecting the alert signal.

This device part provides all necessary filtering without any external component.

The on-chip filtering provides excellent signal-to-noise performance.

The dual-tone alert signal is divided into a high and a low bandpass switched capacitor filters:

- The high alert filter is a 2750 Hz bandpass design, with a notch placed at 2130 Hz for low frequency rejection.
- The low alert filter is a 2130 Hz bandpass design, with a notch placed at 2750 Hz for high frequency rejection.

The filter outputs are smoothed and then limited by high-gain comparators which have hysteresis to reduce sensitivity to unwanted low-level signals, jitter and noise. The outputs of the comparators are square-wave signals.

The two resulting rectangular waves are applied to the digital circuitry where a counting algorithm measures and averages their periods. This averaging prevents dual-tone SCWID simulation by extraneous signals such as voice.

The averaging algorithm has been optimized to provide excellent immunity to “talk-off” and tolerance to the presence of interfering frequencies (third tones) and noise.

When both digital circuitries simultaneously detect a valid tone (2130 Hz and 2750 Hz), the signal applied at the guard-time block goes high. Should the alert tone signal be lost, the input signal at the guard-time block will go low.

### 2.2.3 Guard Time, Overview

To prevent false detection due to talk-off effects and to detect real CAS signals even with drops, a guard-time system is necessary. A guard-time system improves the detection performance and verifies that the duration of a valid signal is sufficient before alerting the microprocessor with an interrupt. It rejects detection of insufficient duration (up guard time) and mask dropouts (down guard time).

There are nine bits for controlling the guard-time block:

- 2 bits, EGT0 and EGT1, for controlling the early guard time
- 2 bits, UGT0 and UGT1, for controlling the up guard time
- 2 bits, DGT0 and DGT1, for controlling the down guard time
- 1 bit, FFD, for controlling the width filter
- 1 bit, FDC, for controlling the drops count
- 1 bit, WP, for enabling the wetting pulse function

One bit is dedicated for enabling the SCWID part.

### 2.2.4 Up Guard Time, Description

The up guard time circuitry prevents false detection from speech or music (talk-off).

The input signal (both 2130 Hz and 2750 Hz) must be continuously high for a duration depending on the 2 programmable bits UGT0 and UGT1.

DGT0	DGT1	UGT Value
0	0	20 ms
1	0	25 ms
0	1	30 ms
1	1	35 ms

If a drop occurs at any time before the selected value, the detection system is cleared.

Nevertheless, there is the possibility to improve such a system using early guard time circuitry.

### 2.2.5 Early Guard Time, Description

The early guard time system, when enabled, helps the up guard time to detect a CAS signal even if there are drops in it. But there are conditions before validating such a polluted signal.

The input signal (both 2130 Hz and 2750 Hz) must be continuously high for duration depending on the 2 programmable bits EGT0 and EGT1.

EGT0	EGT1	EGT Value
0	0	Disabled
1	0	8.5 ms
0	1	10.3 ms
1	1	13.7 ms

After that, the input signal is filtered and a drop can occur without clearing the system if it is not too long. The maximum time value depends on the command filter bit FFD.

FFD	Filter Value (Maximum Drop Duration)
0	2 ms
1	4 ms

If there are too many drops, the system is cleared. The count of drops admitted depends on the command count bit FDC.

FDC	Count Value (Maximum Drop Count)
0	4
1	3

The early guard time with filter and count drops allow a good compromise to achieve talk-off and talk-down immunity.

## 2.2.6 Down Guard Time, Description

The down guard time circuitry prevents drops from speech or music (talk-down).

The input signal (both 2130 Hz and 2750 Hz) must be continuously low for a duration depending on the 2 programmable bits DGT0 and DGT1.

The early guard time is used like for up guard time, but the drop counter is not activated.

\* Note:

The Idle State is an electrical condition into which the TE (when connected to the network) is placed such that it draws minimum current and does not activate the exchange.

DGT0	DGT1	DGT Value
0	0	15 ms
1	0	17 ms
0	1	18 ms
1	1	19 ms

## 2.2.7 Wetting Pulse Function

British Telecom states that the TE is required to apply a DC wetting pulse and an AC load 205 ms after the end of the alerting signal (the Idle State\* Tone Alert Signal); the duration of the wetting pulse is 151 ms; the TE shall rise to a minimum of 25 mA and maintain that current for a total time of not less than 5 ms.

OCTEL3 provides a 15-ms counter (which starts at the end of the alerting signal delayed by the down guard time value) to help the microprocessor to fulfil this requirement.

The signals at the output of the guard time system are sent to the SSB-INTERRUPT treatment.

An interrupt occurs at each edge of the OUT SCWID detector.

When the wetting pulse is enabled (CDE8. mode UK = 1), an interrupt is sent to the microprocessor 15 ms after the falling edge of the WP detector.

Figure 7. Alert detection timing diagram with wetting pulse

## 2.2.8 SCWID: Overview

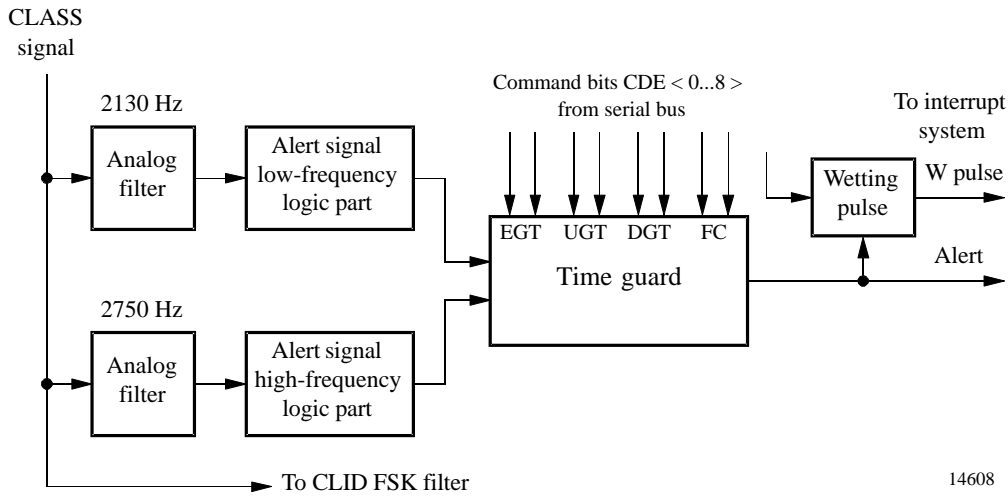

Figure 8. Alert detection

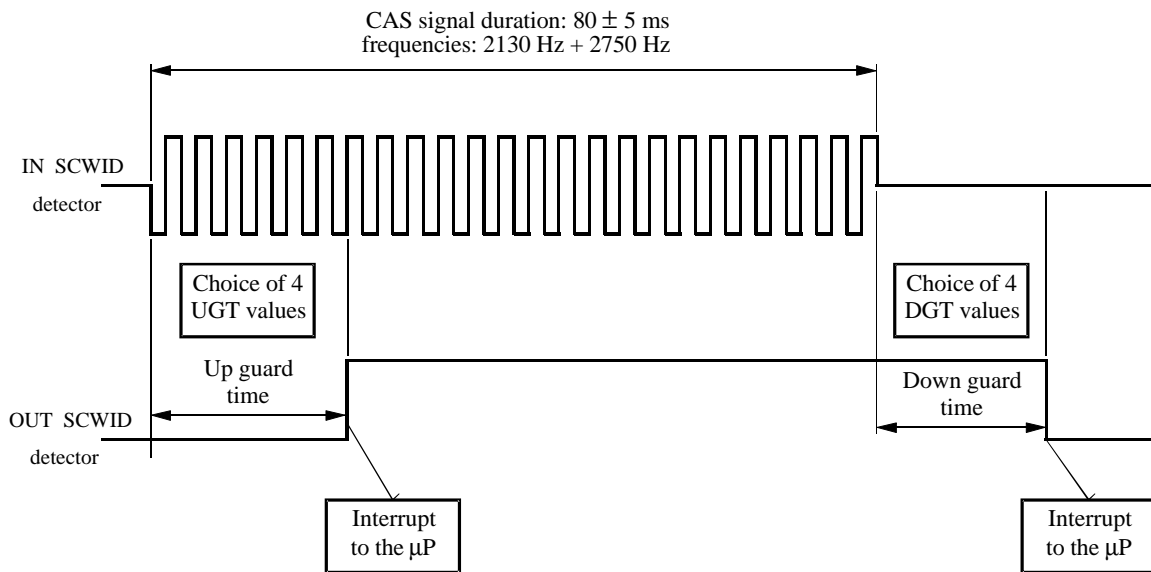

General information:

All the control bits provided for the SCWID function can be modified at any time with the microprocessor.

## 2.2.9 CAS Detect Process

Typical application:

The incoming signal from the CO is not polluted with speech or music. (The feature early guard time is not used)

14609

Figure 9. Timing diagram of standard alert detection

If any drop in the CAS signal occurs before the end of the UGT specified value, then the time counter restarts and the OUT SCWID detector remains low.

If any spike in the blank signal occurs before the end of the DGT specified value, then the time counter restarts and the OUT SCWID detector remains high.

## CAS Detect Process (continued)

Improved process:

To prevent false detection from speech and music by the far and the near end (talk-off), and to detect the incoming CAS signal from the CO, polluted with speech or music by the near end (talk-down), a new feature is used: the early and up guard time.

Figure 10. Timing diagram for early and up guard time

**Note:** In the case above, the EGT counter restarts 3 times. After a successful 10.3-ms EGT, 3 drops occurred but without any effect because the duration and the number is less than the maximum permitted.

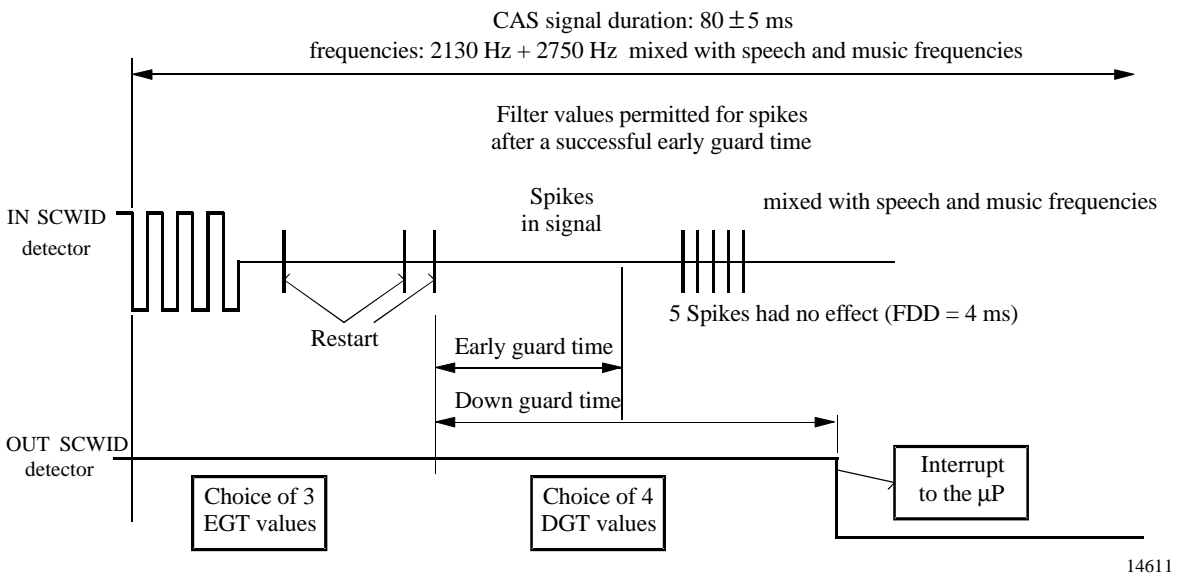

Figure 11. Timing diagram of early and down guard time

**Note:** In the case above, the EGT counter restarts 3 times. After a successful 13.7-ms EGT, 5 spikes occurred but without any effect because the duration is less than the maximum permitted.

## 3 DC Line Interface and Supply-Voltage Generation

The DC line interface consists of an electronic inductance and a dual-port output stage which charges the capacitors at VMPS and VB. The value of the equivalent inductance is given by:

$$L = 2 \times R_{SENSE} \times C_{IND} \times (R_{DC} \times R_{30}) / (R_{DC} + R_{30})$$

The U3900BM contains two identical series regulators which provide a supply voltage VMP of 3.3 V suitable for a microprocessor. In speech mode, both regulators are active because VMPS and VB are charged simultaneously by the DC-line interface. The output current is 6 mA. The capacitor at VMPS is used to provide the microcomputer with sufficient power during long line interruptions. Thus, long flash pulses can be bridged or an LCD display can be turned on for more than 2 seconds after going on-hook. When the system is in ringing mode, VB is charged by the on-chip ringing power converter. In this mode, only one regulator is used to supply VMP with maximum 3 mA.

### 3.1 Supply Structure of the Chip

As main benefit of the U3900BM is the easy implementation of various applications due to the flexible system structure of the chip.

Possible applications:

- Group listening phone
- Hands-free phone
- Phones which feature ringing with the built-in speaker amplifier
- Answering machine with external supply

The special supply topology for the various functional blocks is illustrated in figure 11.

There are four major supply states:

1. Speech condition
  2. Power down (pulse dialing)
  3. Ringing
  4. External supply
1. In speech condition, the system is supplied by the line current. If the LIDET-block detects a line voltage above approximately 2 V, the internal signal VLON is activated. This is detected via serial bus, all necessary the blocks have to be switched on via the serial bus.

For line voltages below 2 V, the switches remain in quiescent state as shown in the diagram.

2. When the chip is in power-down mode (Bit LOMAKE), e.g., during pulse dialing, all internal blocks are disabled via the serial bus, except the oscillator. In this condition, the voltage regulators and their internal bandgap are the only active blocks.
3. During ringing, the supply for the system is fed into VB via the **Ringing Power Converter (RPC)**. Normally, the speaker amplifier in single-ended mode is used for ringing. The frequency for the melody is generated by the DTMF/Melody generator.
4. In an answering machine, the chip is powered by an external supply via Pin VB. The answering machine connections could be directly put to U3900BM. The answering machine is connected to the Pin AMREC. For the output AMREC, an AGC function is selectable via the serial bus. The output of the answering machine will be connected to the Pin AMPB, which is directly connected to the switching matrix, and thus enables the signal to be switched to every desired output.

Figure 12. Supply generator

## 4 Ringing Power Converter (RPC)

The RPC transforms the input power at VRING (high voltage/ low current) into an equivalent output power at VB (low voltage/ high current) which is capable of driving the low-ohmic loudspeaker. The input impedance at VRING is adjustable from 3 kΩ to 12 kΩ by RIMPA ( $Z_{RING} = RIMPA / 100$ ) and the efficiency of the step-down converter is approximately 65%.

## 4.1 Ringing Frequency Detector (RFD)

The U3900BM provides an output signal for the microcontroller. This output signal is always double the value of the input signal (ringing frequency). It is generated by a current comparator with hysteresis. The levels for the on-threshold are programmable in 16 steps and the off-level is fixed. Every change of the comparator output generates a high level at the interrupt output INT. The information can then be read out by means of a serial bus with either a normal or a fast read mode. The block RFD is always enabled.

RINGTH[0:3]	VRING
min. 0	7 V
max. 15	22 V
step	1 V

## 5 Clock Output Divider Adjustment

The Pin OSCOUT is a clock output which is derived from the crystal oscillator of the ceramic resonator. It can be used to drive a microcontroller or another remote component and thereby reduces the number of crystals required. The oscillator frequency can be divided by 1, 8, 16, 32. During power-on reset, the divider will be reset to 1 until it is changed by setting the serial bus.

CLK[0:1]	Divider	Frequency
0	1	3.58 MHz
1	8	447 kHz

### 6.1 Bus Timing

Figure 13. Bus timing

2	16	224 kHz
3	32	112 kHz

## 6 Serial Bus Interface

The circuit is controlled by an external microcontroller through the serial bus. The serial bus is a bi-directional system consisting of a one-directional clock line (BCL) which is always driven by the microcontroller, and a bi-directional data-signal line. It is driven by the microcontroller as well as from the U3900BM (see figure 12). The serial bus requires external pull-up resistors as only open-collector transistors (Pin BDA) are integrated.

**WRITE:** The data is a 12-bit word:

A0 – A3: address of the destination register (0 to 15)

D0 – D7: content of the register

The data line must be stable when the clock is high. Data must be shifted serially.

After 12 clock periods, the write indication is sent. Then, the transfer to the destination register is (internally) generated by a strobe signal transition of the data line when the clock is high (see figure 13).

**READ:**

There is a normal and a fast-read cycle.

In the normal read cycle, the microcontroller sends a 4-bit address followed by the read indicator, then an 8-bit word is read out. The U3900BM drives the data line (see figure 14).

The fast read cycle is indicated by a strobe signal. With the following two clocks the U3900BM reads out the status bits RFDO and LIDET which indicate that a ringing signal or a line signal is present (see figure 15).

## 7 DTMF Dialing

The DTMF generator sends a multi-frequency signal through the matrix to the line. The signal is the result of the sum of two frequencies and is internally filtered. The frequencies are chosen from a low and a high frequency group.

The circuit conforms to the CEPT recommendation concerning DTMF option (rec. T/CF 46-03).

Two different levels for the low level group and two different preemphasis (2.5 dB and 3.5 dB) can be chosen by means of the serial bus.

### 7.1 Melody – Confidence Tone Generation

Melody/confidence tone frequencies are given in the table below.

The frequencies are provided at the DTMF input of the switch matrix. A sinus wave, a square wave or a pulsed wave can be selected by the serial bus. Square signal means output is half of frequency cycle high and half low, so duty cycle of 50% square wave or 50% for pulsed signal.

	DTMFM[0:2]	
0	000	DTMF generator OFF
1	001	Confidence tone melody on (sinus)
2	010	Ringer melody (pulse)
3	011	Ringer melody (square signal)
4	100	DTMF(high level)
5	101	DTMF(low level)
6	110	
7	111	

	DTMFF[0:1] in DTMF Mode	Frequency	Error / %
0	00	697	-0.007
1	01	770	-0.156
2	10	852	0.032
3	11	941	0.316

	DTMFF[2:3] in DTMF Mode	Frequency	Error / %
0	00	1209	-0.110

## 8 Power-on Reset

To avoid undefined states of the system when it is powered on, an internal reset clears the internal registers.

The system (U3900BM + microcontroller) is woken up by any of the following conditions:

VMP > 2.75 V and VB > 2.45 V and

line voltage (VL)

or ringer (VRING)

or external supply (ES)

The power-down of the circuit is caused by a shut-down sent by the serial bus (SD = 1), low-voltage reset or by the watchdog function (see figures 16, 17 and 18).

## 9 Watchdog Function

To avoid the system operating the microcontroller in a wrong condition, the circuit provides a watchdog function. The watchdog has to be retriggered every second by triggering the serial bus (sending information to the IC or other remoted components at the serial bus). If there has been no bus transmission for more than one second the watchdog initiates a reset.

Figure 17. Power-on reset (line)

Figure 18. Power-on reset (ringing)

Figure 19. Power-on reset if low voltage reset enabled

## 10 Acoustic Feedback Suppression

Acoustical feedback from the loudspeaker to the microphone may cause instability of the system. The U3900BM has a very efficient feedback-suppression circuit which uses a modified voice switch topology. Figure 21 shows the basic system configuration.

Two attenuators (TXA and SAI) reduce the critical loop gain via the serial bus either in the transmit or in the receive path. The sliding control in block AFS control (figure 20) determines whether the TX or the RX signal has to be attenuated. The overall loop gain remains constant under all operating conditions.

Selection of the active channel is made by a comparison of the logarithmically compressed TX- and RX- envelope curve. Figure 20 shows the AFS control.

The system configuration for group listening, which is implemented in the U3900BM, is illustrated in figure 22. TXA and SAI represent the two attenuators, whereas the logarithmic envelope detectors are shown in a simplified way (operational amplifiers with two diodes).

Receive and transmit signals are first processed by logarithmic rectifiers in order to produce the envelopes of the speech at TLDT and TLDR. After amplification a

decision is made by the differential pair as to which direction should be transmitted.

The attenuation of the controlled amplifiers TXA and SAI is determined by the emitter current  $I_{AFS}$  which is bus programmable.

Figure 20. AFS control

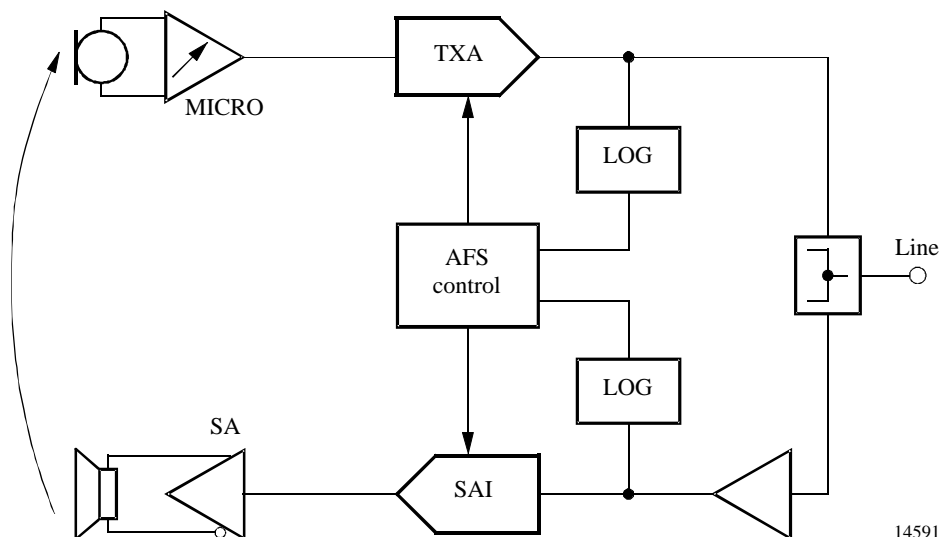

Figure 21. Basic system configurations

Figure 22. System configuration for group listening

## 11 Analog-to-Digital Converter (ADC)

The circuit is a 7-bit successive approximation analog-to-digital converter in switched capacitor technique. An internal bandgap circuit generates a 1.25-V reference voltage which is the equivalent of 1 MSB. 1 LSB = 19.5 mV. The possible input voltage at ADIN is 0 to 2.48 V.

The ADC needs an SOC (Start Of Conversion) signal. In the 'High' phase of the SOC signal, the ADC is reset. 50 μs after the beginning of the 'Low' phase of the SOC signal the ADC generates an EOC (End Of Conversion) signal which indicates that the conversion is finished. The rising edge of EOC generates an interrupt at the INT output. The result can be read out by the serial bus.

Voltages higher than 2.48 V have to be divided. The signal which is connected to the ADC is determined by 5 bits ADC0, ADC1, ADC2, ADC3 and NWT. TLDR/TLDT measuring is possible relative to a preceding reference measurement. The current range of IL can be doubled by ADCR. If ADCR is 'High', S has the value 0.5, otherwise S = 1.

The source impedance at ADIN must be lower than 250 kΩ.

Accuracy: 1 LSB ± 3%

D = measured digital word ( $0 <= D <= 127$ )

S = programmable gain 0.5 or 1

Vp = peak value of the measured signal

## 12 Switch Matrix

The switch matrix has 5 inputs and 5 outputs. Every pair of input and output can be connected. The inputs and outputs used must be enabled. If 2 or more inputs are switched to an output, the sum of the inputs is available at the output. The inputs MIC and LRX have offset cancellers with a 3-dB corner frequency of 270 Hz. AMPB and CMIC have a 60-kΩ input impedance. The TXO output has a digitally-programmable gain stage with a gain of 2, 3 to 9 dB depending on AGATX0 (LSB), AGATX1, AGATX2 (MSB) and a first-order low-pass filter with 0.5 dB damping at 3300 Hz and 3 dB damping at 9450 Hz. The outputs RXLS, EPO and CEAR have a gain of 0 dB. If a switch is open, the path has a damping of more than 60 dB.

### 13 Sidetone System

The Sidetone Balancing (STB) has the task to reduce the crosstalk from LTX (microphone) to LRX (earpiece) in the frequency range of 0.3 to 3.4 kHz. The LTX signal is converted into a current in the MOD block. This current is transformed into a voltage signal (LINE) by the line impedance ZL. The LINE signal is fed into the summing amplifier DIFF1 via capacitor CK and attenuator AMP1.

On the other side the LTX buffered by STOAMP drives an external low-pass filter (RST, CST). The external low-pass filter and the internal STB have the transfer function drawn in the STB box. The amplified STB-output signal drives the negative input of the summing block. If both signals at the DIFF1 block are equal in level and phase, we have a good suppression of the LTX signal. In this condition the frequency and phase response of the STB block will represent the frequency curve on line.

In real live the line impedance ZL varies strongly for different users. To reach a good suppression with one application for all different line impedances, the STB function is programmable.

The 3 programmable parameters are

1. LF (gain at low frequency).  
LF has 15 programming steps. LF(0) gives -2 dB gain, LF(15) gives 5.5 dB gain.

LF	0	1	2	3	4	5	6	7
Step gain	-2	-1.3	-0.6	0.1	0.6	1.0	1.3	1.6

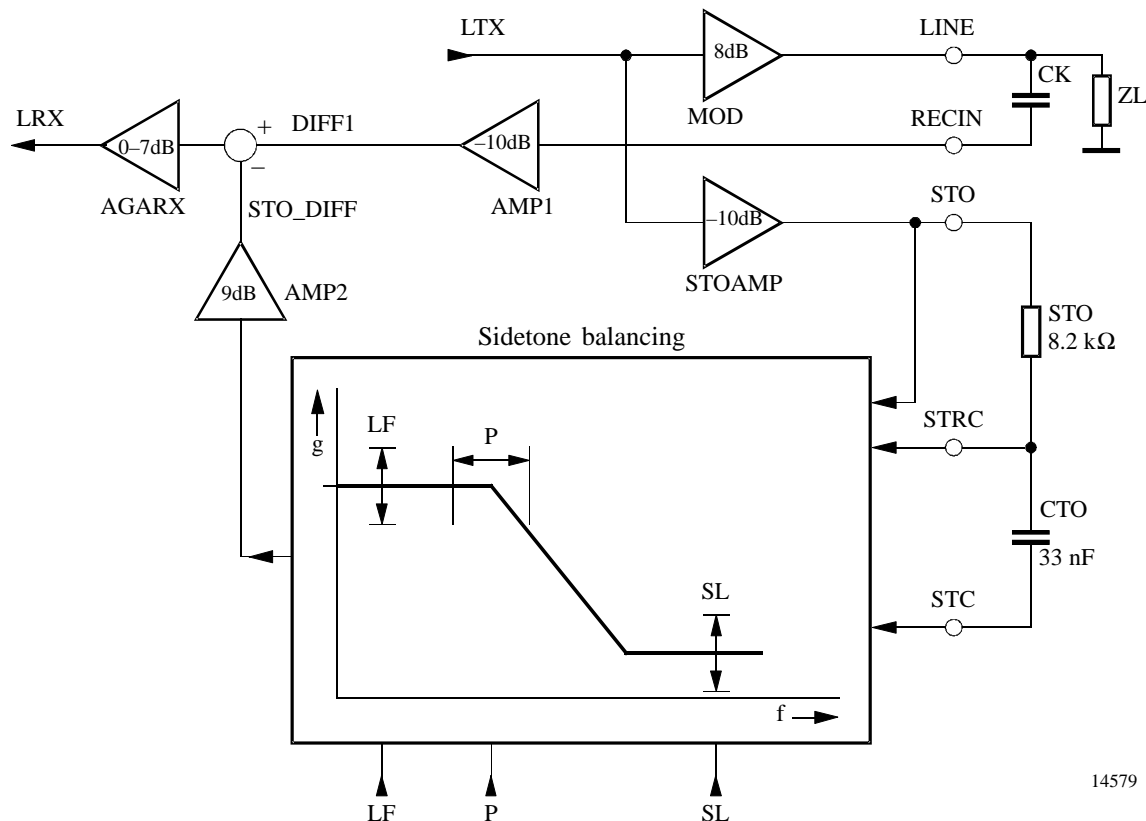

LF	8	9	10	11	12	13	14	15
Step gain	1.9	2.2	2.5	3.0	3.6	4.2	4.8	5.5

$$STO\_DIFF(LF) = (-10 \text{ dB} - 2 \text{ dB} + 0.5 \text{ dB} \times LF + 9 \text{ dB}) \times LTX$$

2. P (the pole position of the lowpass).  
The P adjustment has 31 Steps. P(0) means the lowpass determined by the external application (RST, CST). The internally processed low-pass frequency is fixed by this equation.

$$f(P) = \frac{1}{2 \times \pi \times CST \times RST} \times 1.122^P$$

3. SL (sidetone slope; the pole frequency of the highpass)  
The SL have 3 steps. SL(0) is a lower frequency of the highpass. SL(3) is a higher frequency of the highpass. With SL we can influence the suppression at high frequencies.

## Ozone Depleting Substances Policy Statement

It is the policy of **Atmel Germany GmbH** to

1. Meet all present and future national and international statutory requirements.
2. Regularly and continuously improve the performance of our products, processes, distribution and operating systems with respect to their impact on the health and safety of our employees and the public, as well as their impact on the environment.

It is particular concern to control or eliminate releases of those substances into the atmosphere which are known as ozone depleting substances (ODSs).

The Montreal Protocol (1987) and its London Amendments (1990) intend to severely restrict the use of ODSs and forbid their use within the next ten years. Various national and international initiatives are pressing for an earlier ban on these substances.

**Atmel Germany GmbH** has been able to use its policy of continuous improvements to eliminate the use of ODSs listed in the following documents.

1. Annex A, B and list of transitional substances of the Montreal Protocol and the London Amendments respectively
2. Class I and II ozone depleting substances in the Clean Air Act Amendments of 1990 by the Environmental Protection Agency (EPA) in the USA
3. Council Decision 88/540/EEC and 91/690/EEC Annex A, B and C (transitional substances) respectively.

**Atmel Germany GmbH** can certify that our semiconductors are not manufactured with ozone depleting substances and do not contain such substances.

**We reserve the right to make changes to improve technical design and may do so without further notice.**

Parameters can vary in different applications. All operating parameters must be validated for each customer application by the customer. Should the buyer use Atmel Wireless & Microcontrollers products for any unintended or unauthorized application, the buyer shall indemnify Atmel Wireless & Microcontrollers against all claims, costs, damages, and expenses, arising out of, directly or indirectly, any claim of personal damage, injury or death associated with such unintended or unauthorized use.

**Data sheets can also be retrieved from the Internet: <http://www.atmel-wm.com>**
